

response.⁸ The damage to the epithelium could trigger the following cascade: 1) Entrapment of epithelial cells in the papillary dermis, 2) Subsequent degeneration of these cells and lipid formation, 3) Engulfment of released lipids by macrophages, and 4) Accumulation of foam cells between the rete ridges. On the other hand, it was speculated that the Human Papillomavirus (HPV) was involved in the pathogenesis of VX. Khaskhely et al. reported VX in which HPV type 6a DNA was detected in the lesional tissues by Polymerase Chain Reaction (PCR) and sequence analysis.⁷ By contrast, another study examined HPV types 6, 11, 16, 18, 31, 33, and 35 by PCR, which were all negative.⁹ In the present case, PCR amplification of HPV including serotypes 6, 11, 16, 18, 31, 33, 35, 52b, and 58 was performed, with all negative results. Therefore, further studies of the etiology of VX are necessary.

Case for diagnosis. Unilateral nodule on the nipple: erosive adenomatosis of the nipple[☆]

Dear Editor,

A 44-year-old Hispanic woman came to our dermatology clinic with an asymptomatic exophytic lesion on her right nipple that had been present for two years. There was no family history of breast cancer. The lesion started as a small erythematous plaque that gradually grew and developed a focal erosion. On dermatological examination, a 1.0 × 1.0 cm hard erythematous ill-defined lesion with a central erosion was noticed. Dermoscopy showed pink-white clouds and red structureless areas (Fig. 1). There was no lymphadenopathy or nipple retraction.

An incisional biopsy of the right nipple was performed. Histopathology revealed a well-circumscribed dermal tumor with adenomatous and papillary configuration. The tumor consisted of multiple ductal structures lined by a double layer of columnar eosinophilic cells, some of which showed secretion by cell decapitation. A basal layer of myoepithelial cells was present. A ductal opening communicated with the surface epithelium at one end. No cellular atypia or pleomorphism was noticed (Fig. 2).

What is your diagnosis?

- a) Paget's disease of the breast;
- b) Contact dermatitis;
- c) Ductal carcinoma;
- d) Erosive adenomatosis of the nipple.

Discussion

Erosive Adenomatosis of the Nipple (EAN), also known as nipple adenoma, papillary adenoma of the nipple, or florid

[☆] Study conducted at the General Hospital "Dr. Manuel Gea González", Mexico City, Mexico.

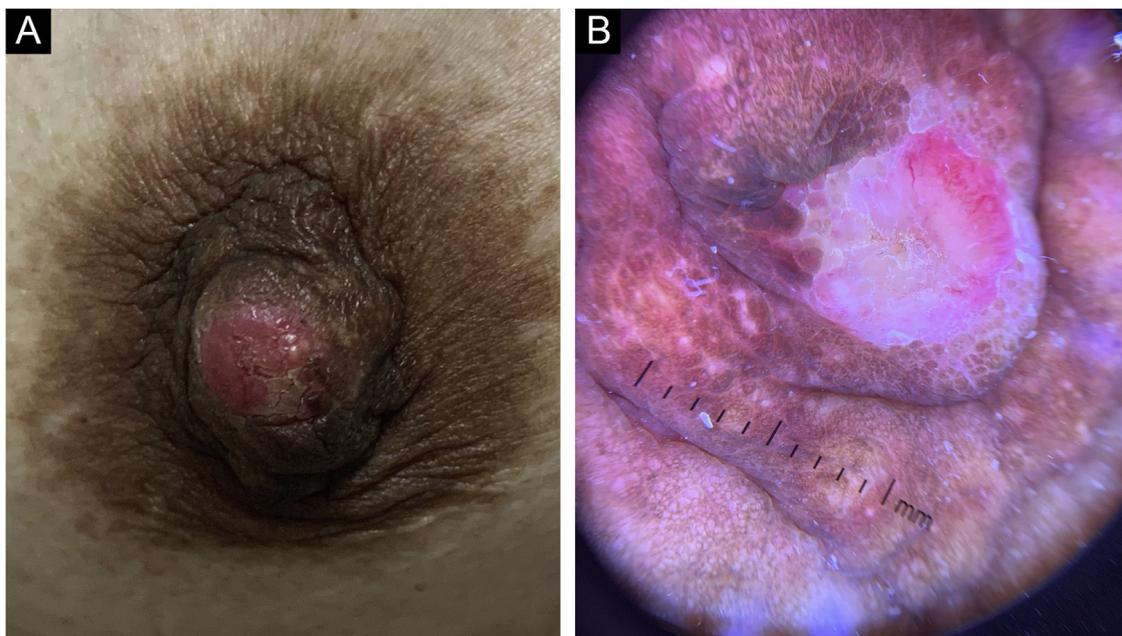

Figure 1 (A) A firm nodule with a central erosion on the right nipple. (B) Dermoscopy showed pink-white clouds and red structureless areas

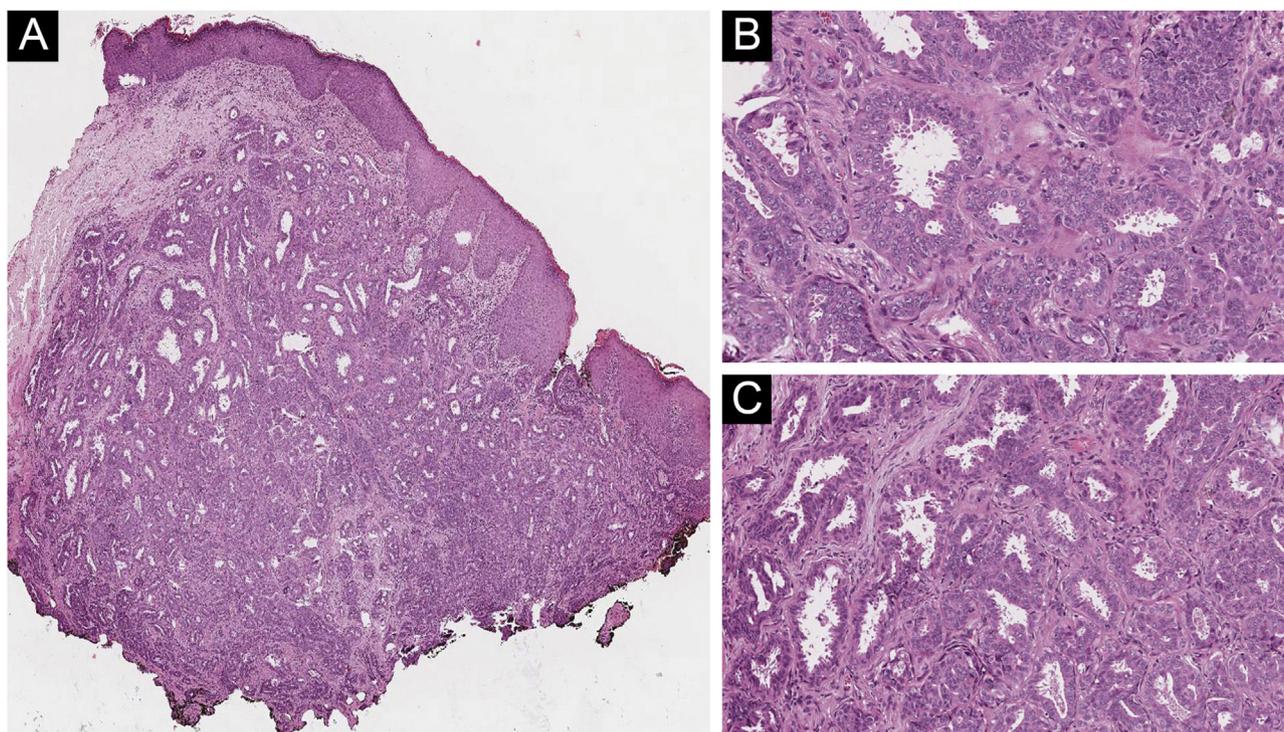

Figure 2 (A) Histology showing a well-circumscribed, non-encapsulated dermal glandular proliferation (Hematoxylin & eosin, $\times 100$). (B–C) Ductal structures lined with cuboidal epithelial cells, which present apocrine secretory projections on its luminal border (Hematoxylin & eosin, $\times 400$)

papillomatosis, is an uncommon benign epithelial tumor that originates from the lactotrophic ducts of the nipple-areola complex. It was first reported as a benign intraductal papilloma in 1951 by Haagensen et al.^{1,2}

Like our patient, it affects middle-aged women, with an average age of 43 to 45 years which is uncommon in men.²

Clinically it presents as an erythematous unilateral mass with a partial or complete erosion with serous or serosanguineous discharge. In advanced stages, the nipple becomes

enlarged, thickened, and indurated and may present as a big exophytic mass.³

Mammary Paget disease may also present with a nipple tumor with erosion and serosanguineous discharge, and it is often associated with ductal carcinoma in situ.⁴ Thus, the most important differential diagnoses include mammary Paget's disease and breast ductal carcinoma, however other inflammatory (contact dermatitis eczema) and infectious diseases may mimic EAN.

The histological findings are the most valuable evidence in differentiating EAN from these inflammatory and malignant mammary tumors. Histopathology reveals a glandular, well-circumscribed, non-encapsulated proliferation coated by a characteristic double layer of cells composed of an external layer of cubic or flattened myoepithelial cells and an internal layer of cuboidal or cylindrical epithelial cells, which can present apocrine secretory projections on its luminal border.¹ The absence of cytologic atypia is an important feature.

Surgical excision with nipple resection is the therapy of choice. The Mohs micrographic surgery and nipple splitting enucleation procedure can entirely remove the tumor while preserving the appearance and functionality of this vital location.⁴ Other authors have reported favorable treatment outcomes with cryosurgery and photodynamic therapy.^{5,6}

Identification of this lesion is critical because of clinical and therapeutic implications, unnecessary mastectomy or extensive surgeries may be carried out if misdiagnosed. Our patient was treated with complete excision of the tumor with no recurrence in a 1-year follow-up.
